WALL EFFECTS

LIMITATION OF EDDY SIZE/TRANSPORT BY

- wall proximity
- stratification

HANDLING OF GROUND PROXIMITY EFFECTS

- 1-D models: log-linear vertical spacing distribution (e.g. Taylor & Delage, BLM 1971)
- NWP: bulk parameterization of the surface layer
- EULAG: explicit specification of the heat flux as a boundary condition

HANDLING OF STABLE STRATIFICATION EFFECTS

- 1-D models & NWP: diverse parameterizations
- EULAG: ??? (a subgrid issue)

EXPECTATIONS

- consistency of the surface layer parameterization with the subgrid turbulence scheme
- possible adaptation for inclined terrain
- applicable for both the LES & NWP (quasi-hydrostatic) modes (see Cuxart et al, QJRMS 2000)

QUESTIONS

IS THERE A VIABLE PHYSICAL EXPLANATION?

Yes. The issue can be related to existence of a maximum heat flux for a given wind speed under stable stratification. The heat flux is zero under neutral conditions, and if it vanishes at extreme stability, there should be a maximum.

IS IT A KNOWN PHENOMENON?

Yes. It was noted by Taylor (QJRMS 1971), and Carson and Richards (BLM 1978). However, very few papers mention it.

Perspectives

Length scale issue

QUESTIONS

HAS IT EVER BEEN NOTICED IN REALITY?

It seems so. Malhi (BLM 1995) presents experimental data which seem to support the existence of a maximum.

WHAT IS THE PHYSICAL MEANING OF THE TWO SOLUTIONS?

Are there corresponding different scenarios in the nature?

- Frequently, we observe either intense and shallow ground-based inversions, or much deeper nocturnal boundary layers with small temperature difference.
- Modelers are familiar with a “runaway cooling” phenomenon.

Perspectives

Length scale issue

QUESTIONS

CAN IT BE A MORE GENERAL PROBLEM?

Is this problem specific to the surface layer and its bulk parameterization? Perhaps it is a more general problem of turbulence (parameterization) in the entire SBL?

IS IT IMPORTANT?

- How frequently it happens?
- What are the consequences?

CONCLUSIONS & DISCUSSION

DUAL SOLUTIONS:

- do not necessarily arise from the log-linear nondimensional wind profile (as shown by Malhi, 1995)
- are not an endemic feature of the surface layer - they may be reproduced by the turbulence closure model regardless of height.
- are associated with the existence of the critical value of the gradient Richardson number. Existence of such critical value is now disputed (e.g. Galperin et al. (2007), Zilitinkevich and Esau (2007), Mahrt (2010))

CONCLUSIONS & DISCUSSION

DUAL SOLUTIONS:

- apparently are not related to different cooling scenarios
- apparently are not associated with model instabilities at the surface

MOREOVER,

- We see that zone where the critical flux Richardson number is maintained, is separated from the ground with a layer, where wind shear is present and subcritical regime is maintained.
