

Appendix D: Cray Job Decks

D.1 Purpose

The job decks (shell scripts) are used to run the MM5 modeling system programs. Job decks for NCAR Crays (paiute, ouray, or chipeta) are written in C-shell, and can be used in either batch or interactive mode. Users with syntax questions for C-shell constructs should refer to man page for “csh”. New Cray users should browse through NCAR/Scientific Computing Division’s (SCD) UNICOS users’ guide (URL: http://www.scd.ucar.edu/docs/UNICOS/unicos_guide.toc.html) to get familiar with the Cray environment. Questions regarding Cray usage should be directed to SCD consultant at consult1@ucar.edu. For information on obtaining an computer account at NCAR, please visit SCD’s Web page: <http://www.scd.ucar.edu/css/resources/requesthome.html>.

The modeling system job decks are structured similarly to each other. The discussion in this section is focused on describing the general structure of the job deck. Shell variables that are common throughout the MM5 modeling system job decks are discussed. The examples are taken from the TERRAIN, DATAGRID, RAWINS, INTERP, GRAPH, and MM5 job decks located in the

`~mesouser/MM5V2`

directory seen on ouray/paiute/chipeta or /mesouser/MM5V2 directory on NCAR’s anonymous ftp (<ftp.ucar.edu>).

D.2 Prerequisite

There are several things a user needs to prepare before starting running jobs on NCAR’s Crays.

- Make sure your .cshrc file is up-to-date and contains the following:

```
# Initialize modules
  if (-f /opt/modules/modules/init/csh ) then
    source /opt/modules/modules/init/csh
    module load modules PrgEnv
    module load modules nqe
  endif
and
  setenv NCARG_ROOT /usr/local
```

This enables a user to use Cray utilities (such as the compiler) and NCAR Graphics. The environment variable **NCARG_ROOT** is required on a workstation where NCAR Graphics is available.

- Make sure you have an up-to-date .rhosts file on both your local machine and Crays. A typical .rhosts file looks like this:

```
paiute.ucar.edu username
ouray.ucar.edu username
```

- Make sure that you browse through the `~mesouser` directories on the Crays, or `mesouser/` directory on anonymous ftp. All job decks, program tar files, data catalogs, and utility pro-

grams reside in the directory.

D.3 Functions of Job Decks

The general job deck construct and functions are the following:

- batch job commands that are used for Crays to request CPU time and memory
- input/output pathnames to retrieve and archive data files
- job switches and output options
- where to obtain Fortran program tar files
- parameter statements used in Fortran programs to define domain and data dimensions
- FORTRAN namelist used during program execution to select runtime options
- a section that does not normally require user modification

All Cray job decks are structured similarly. Each deck begins with a number of QSUB commands required for batch job execution on a Cray. It is followed by shell variables needed to set up data input and output pathnames, job switches, and your source code location, etc. The next section of a job deck contains PARAMETER statements required for Fortran programs, and namelist used during execution. The remaining job deck, which handles the data input, generation of the executable from the FORTRAN source code, and data archival, does not typically need user modification. A user needs only to modify this section to adjust the default setting for running the modeling system on other site.

If a user plans to work on NCAR's Crays, all he/she needs to acquire are the job decks from the `~mesouser/MM5V2` directory. These decks will enable a user to run in batch as well as in interactive mode on the Cray. When using these decks interactively, `cd` to `$TMPDIR` (this directory will disappear when one logs off), and copy the tar files to the directory before running.

D.4 What to Modify in a Job Deck?

D.4.1 Batch Job Queueing Commands

Each of the Cray job decks has several lines of header commands for the UNICOS network queueing system. Inclusion of these commands allows the decks to be submitted into the batch queue locally on the Cray with "qsub" command (e.g. `qsub my.job`), or remotely from a user's front-end machine through IRJE or MIGS (see usage on <http://www.scd.ucar.edu/docs/catalog/>). The QSUB commands inside the job decks are preceded by the "#" character; when these jobs are run interactively, the QSUB commands are interpreted as comments.

```
# QSUB -r DATAGRID      # request name
# QSUB -reg              # job queue class
# QSUB -eo              # stdout and stderr together
# QSUB -lM 5Mw          # maximum memory
# QSUB -lT 300          # time limit per request
# QSUB                  # no more qsub commands
#
ja
set echo
#
```

```

# Define the batch output name
#
batchname datagrid.out
#
# *****
# *****      datagrid batch C shell      *****
# *****      V2 System                    *****
# *****      for both cf77 and f90        *****
# *****
#
#   This version of the DATAGRID job deck can process the model first guess
#   fields for all domains in one DATAGRID submittal
#
# .....
#
if ( $ENVIRONMENT == BATCH ) then
    cd $TMPDIR
endif

```

#QSUB “option value”

This syntax is a shell command that specifies the UNICOS Network Queuing System (NQS) options for batch jobs. If the script is executed interactively, the QSUB will be ignored by the shell. The NQS ‘option values’ listed in the shell script that require user's modification are described below

#QSUB -q queue:

This option sets the queue. The available NCAR/Cray job queues are listed in NCAR SCD documentation (the URL is <http://www.scd.ucar.edu/docs/UNICOS/04.nqs.html>).

#QSUB -IM nMw:

This sets the maximum memory used by the job. The value n has the unit of mega words. For non-dynamical-memory-allocated programs, the memory required by a job can be estimated by using the ‘size’ command: *size program.exe*, for example.

#QSUB -IT n:

This is the maximum CPU time, in seconds, required by the entire script (including data transfer to and from MSS, no grace period).

If the program begins execution and subsequently fails with either of the two following error messages,

```

not enough space
cpu limit exceeded

```

the user should resubmit the job deck after augmenting the memory allocation to increase space (**#QSUB -IM**) and/or the CPU time limit (**#QSUB -IT**).

ja:

This UNICOS command starts the UNICOS job accounting information.

set echo:

Echoes commands executed in the script. Useful for checking job status when it fails.

cd \$TMPDIR:

When this command is executed in a batch job deck, a temporary directory is created when the job execution begins. The directory has a name nqs.+++++XXXX, where XXXX are an assigned number/letter combination. No files are scrubbed from \$TMPDIR until all of the initiated processes have completed, then all files are removed and the directory is deleted at the end of the job. (You can also use this command to create a temporary working directory when you log in. In this case, the directory will bear a name jtmp.XXXXXXXa, where XXXXXX is a 6-digit integer. This directory will disappear when you log off.)

D.4.2 Shell Variables

After the QSUB commands, the next user modification is the shell variables that are used to set up NCAR Cray's Mass Storage System (MSS) pathnames, remote machine name for copying files (rcp), and job switches. The job decks have all of the optional settings available, with the inactive lines commented (with a # at the first column).

- MSS related set up

On NCAR's Cray, the input and output files generated by the MM5 modeling system are stored on MSS. Users need to set up the MSS pathname for the input and output files so the script can retrieve the input files prior to the execution of the program, and store the output files after the program is completed. For complete information on how to use the MSS facility at NCAR, please review SCD's online documentation: <http://www.scd.ucar.edu/docs/catalog/cat.mss.html>. Usage of MSS is charged against your GAUs allocation. If you are running the job decks on other Cray which doesn't have MSS, the MSS related shell variables can be defined as a pathname to a data disk. Example:

```
set ExpName = TEST/EXP1          # MSS pathname
set RetPd = 365                  # Retention period in days for MSWRITES
#
#      MSS filenames for terrain data sets
#
set InTerr    = ( ${ExpName}/TERRAIN_DOMAIN1 )
#
set InAnly = /DSS/xxxxxx        # MSS Filename(s) for NMC analyses
set InSnow   # MSS Filename for additional snow-cover file (optional)
```

ExpName:

This is used to set up the MSS input and output pathname, and is recommended to use something that describes the experiment. A user should use the same ExpName for every job decks in the MM5 modeling system for a single experiment. If ExpName doesn't start with a /, then NCAR Crays' login name as MSS root name (upper case) is assumed.

RetPd:

It is used to set the retention period in days for the MSS files. This is one of the options for the local NCAR mswrite command. The upper limit for retention period is 32767 days.

InX, OutX:

One of the conventions used to denote input files from output files is the name given to the shell variable holding the MSS path locations. Shell variables starting with the string “In” are files coming from the MSS; they are inputs to a program. Shell variables starting with the string “Out” are to be achived to the MSS; they are outputs from a program. The same MSS file can be an output file from one of the job decks, and then be an input file in a subsequent program. In a normal submittal, the **InX** and **OutX** variables do not need to be changed. However, if a user needs to input a MSS file under other user's login name, these variables need to be modified. (Note that **InX** and **OutX** only provide the MSS pathname, the file names are hard-wired in the section of the shell scripts that does not typically require user modification. For example, an output file from program TERRAIN would be TEST/EXP1/TERRAIN_DOMAIN1.)

- RCP set up

The rcp command copies files between machines. In the deck, it is mostly used for situations such that you have a modified source code tar file located on your local machine, or getting some output files to your local machine (e.g. the plot file from TERRAIN, or auto bogus output from RAWINS). A shell variable **Host** is defined to set up the path for rcp:

```
set Host      = username@host.domain:directory
```

Host and domain:

They are used to remotely copy files to and from NCAR's Cray to user's local machine. The shell variable Host should have a form of **username@host.domain:directory**, where **username** is user's login name on the user's local machine, **host** and **domain** are local machine's name and address, and **directory** is the directory to copy a file to or from. If the user's local login name is the same as the login name on NCAR's Cray, username may be eliminated.

In order for the remote shell facility to work on another machine without logging on, such as rcp, you must have a file called *.rhosts* in the login directory on each remote machine that you want to copy files to or from. The *.rhosts* file should contain a list of machine and username pairs:

```
host1.domain1 username1
host2.domain2 username2
```

For example, if mesouser wants to have remote access between NCAR's ouray and local machine mmm1 and mmm2, the *.rhosts* file on ouray should have the following lines

```
mmm1.mmm.ucar.edu mesouser
mmm2.mmm.ucar.edu mesouser
```

and the *.rhosts* file on machines mmm1 and mmm2 should have the lines

```
ouray.ucar.edu mesouser
ouray mesouser
```

Note that in this example there are two entry lines for ouray. The user needs to test out on their local machine to see whether only one is needed. The user also needs to protect their *rhosts* files to avoid security problem by using the following command

```
chmod 600 .rhosts
```

If mesouser wants to rcp a file back to machine mmm1 under directory /usr/tmp/mesouser, the Host variable should be set to

```
set Host = mesouser@mmm1.mmm.ucar.edu:/usr/tmp/mesouser
```

- Job Switches

Since the MM5 modeling system is designed for multiple applications, there are many options on how a job may be run. These options include different sources for input meteorological data, ways to do objective analysis, running the model hydrostatically or nonhydrostatically, and whether the job is an initial or restart run, etc.. A user is required to go through the shell variables and make selection of job switches. The following is an example taken from the *datagrid.deck*, and the selection is with regarding to the type of global analysis to be used to create the first guess fields:

```
#
#      type of datagrid job
#
# set Analysis = NMC           # NMC first guess
# set Analysis = ECMWF        # Old ECMWF format first guess
set Analysis   = TOGA         # ECMWF TOGA format first guess
# set Analysis = UNIDATA      # Unidata first guess (NMC MRF)
#
```

This table lists the shell variables that need to be defined by users for each program of the MM5 modeling system:

<i>Program Name</i>	<i>Shell Variables</i>
TERRAIN	TerPlt
DATAGRID	Analysis, SST
RAWINS	Submit, INOBS, SFCsw, BOGUSsw
INTERP	HYDROsw, ForBsw, NESTsw
MM5	compile, execute, STARTsw, FDDAsw, HYDROsw

These shell variables will be discussed in detail in the other chapters of this document.

- IEEE format data output option

The IEEE data are standard data format to use on a workstation. An option to output data in IEEE format from the MM5 modeling system programs TERRAIN, DATAGRID, RAWINS, and INTERP is provided in the shell by setting

```
OutIEEE = yes
```

It makes use of a shell script *ieee.csh* copied from `~mesouser/Util` directory to convert MM5 modeling system output to IEEE format data.

D.4.3 Accessing Source Code

Typically this is the way source code tar files are accessed in a (batch) Cray job deck:

```
#
#       Where is your source code?
#
#   set UseMySource = yes
#   set UseMySource = no
#
#   ----- GET RAWINS TAR FILE -----
#
if ( $UseMySource == yes ) then
    rcp $Host/rawins.tar .
    tar -xf rawins.tar
else if ( ( $UseMySource == no ) && ( $ENVIRONMENT == BATCH ) ) then
    msread rawins.tar.Z /MESOUSER/MM5V2/RAWINS/RAWINS.TAR.Z
#   cp /fs/othrorgs/home0/mesouser/MM5V2/Rawins/rawins.tar.Z .
    uncompress rawins.tar
    tar -xf rawins.tar
endif
rm rawins.tar
```

As an example, the files contained in program RAWINS tar file is listed below:

CHANGES	Description of changes to the program
Diff/	Will contain difference files between consecutive releases
Makefile	Makefile to create the program executable
README	General information about the program directory
Templates/	Job deck directory
con.tbl	Table file for plots
configure.make.f77	Rules for the Makefile using cf77
configure.make.f90	Rules for the Makefile using f90
map.tbl	Table file for plots
src/	Program source code directory

D.4.4 Parameter Statements

The unix *cat* command is used to create FORTRAN include files, which are typically used to define the parameterized dimensions for a FORTRAN program. These are direct modifications to the source code, implying that strict FORTRAN syntax must be observed. Most programs require users to set up the parameter statements. The usage of *cat* is shown below:

```
cat > src/param.incl << EOF
    PARAMETER (.....)
    .....
EOF
```

As an example, the following is taken from *datagrid.deck*:

```
cat > src/paramdim.incl << EOF
```

```
C
C  IMX AND JMX MUST BE GREATER THAN OR EQUAL TO THE MAXIMUM I AND J
C  DIMENSIONS OF ANY DOMAIN (EXPANDED OR NOT EXPANDED) THAT DATAGRID
C  WILL PROCESS.
C
      PARAMETER ( IMX=35, JMX=38 )
C
EOF
```

D.4.5 Fortran Namelist

The MM5 modeling system uses FORTRAN namelist to provide a way of selecting different options without re-compiling the program. The unix *cat* command is used to create namelist files from the shell script during the execution of the shell script. The variables in the namelist are described in detail in other chapters of this document specific to those individual programs. The format is the following

```
cat >! xxxx << EOF
&.....
.....
& ;-----
EOF
```

Since the namelist is not a ANSI 77 standard, the FORTRAN 77 compiler used by different machines may have different syntax for the namelist.

```
&DATIME ;-----DATE AND TIME INPUT-----
IYEAR  = 1993,                ; Year (4-digit) of the start time.
IMONTH  = 03,                 ; Month of the start time.
IDAY    = 13,                 ; Day of the start time.
IHOURL  = 00,                 ; Hour of the start time.
;
IFILES  = 2,                  ; NUMBER OF TIMES TO PROCESS
ITIMINT = 12,                 ; TIME INTERVAL (HOURS) (Usually 12 for
histor-                        ; ical data. May be set to 6 for Unidata
input)
;
& ;-----
EOF
#
#####
#####
#####      END USER MODIFICATION      #####
#####
#####
#####
```

After the user has 1) modified the QSUB commands to set the proper class for the job, 2) correctly set the shell variables for the switches and MSS pathnames, 3) modified the parameter statements, and 4) set up the FORTRAN namelist, there is typically no more user modification required in the deck. The rest of the script can be treated as a black box.

D.5 What is in the Remainder of a Job Deck?

D.5.1 Acquiring Input Files from the Mass Storage System

Syntax:

```
msread local-filename MSSfilename
```

where *local-filename* is the filename in the current directory, and *MSS filename* is the filename on MSS.

Example:

```
#  
#      terrain files  
#  
set NUM = 1  
while ( $NUM <= $#InTerr )  
    if ( ! -e terrain.${NUM} ) then  
        echo "  msread terrain.${NUM} $InTerr[$NUM] "  
        msread terrain.${NUM} $InTerr[$NUM]  
    endif  
    @ NUM ++  
end
```

msread:

This is a local NCAR command that copies an MSS file to UNICOS disk.

D.5.2 Setting Up Fortran Input and Output Units

Syntax:

```
assign -a filename [options] Fortran-unit
```

If no option is specified, the file must be Cray binary. If the file is 32-bit IEEE, the syntax becomes:

```
assign -a filename -Ff77 -Nieee Fortran-unit
```

Another way to setup input and output units is to use unix command *ln*:

```
ln -s filename Fortran-unit
```

This command makes a 'link' between filename and Fortran-unit.

Example:

```
#  
#      set up fortran input files for DATAGRID  
#  
if ( -e assign.datgrd ) rm assign.datgrd  
setenv FILENV assign.datgrd  
if (( $?SST ) && ( $SST == NAVY )) then  
    assign -a navysst          fort.3
```

```
else if ( ( $?SST ) && ( $SST == CLIM ) ) then
    assign -a climsst          fort.12
endif
```

assign -a aliasfile:

This is a Cray utility that is used to assign FORTRAN files to FOTRAN units. The option *-a* expects actual file name to follow.

D.5.3 Creating FORTRAN Executable

Unix *make* utility is used to generate FORTRAN executable in the MM5 modeling system. The rules and compile options a *make* command uses are contained in the file: *configure.make* for programs TERRAIN, DATAGRID, RAWINS, INTERP and GRAPH, and *configure.user* for program MM5. For more information on make, please see Chapters 3 and 10 of this document.

D.5.4 Execution

```
X.exe >&! X.print.out
```

Where X is the program name. Example:

```
#
#      run DATAGRID
#
date
if ( -e acct ) rm acct
datagrid.exe >&! datagrid.print.out
ja -s >! acct
cat acct >> datagrid.print.out
```

date:

This command prints the dates.

ja -s:

This UNICOS command ends the job accounting information. The *-s* option produces the summary report.

D.5.5 Save Files

When a job is completed, some files used in and output from the execution of a program are archived on MSS using the tar command:

```
tar -cf X.tar .....
```

An example:

```
tar -cf datagrid.out.tar src/datagrid.exe datagrid.namelist datagrid.print.out
```

D.5.6 Writing Output Files to Mass Storage System

Syntax:

```
mswrite -t $RetPd local-filename MSSfilename
```

Example:

```
set test = `ls -l rawanl.out`
if ( $test[5] < 6000000000 ) then
    mswrite -t $RetPd rawanl.out ${OutRaw}/RAWINS_DOMAIN${DomId}
    echo mswrite -t $RetPd rawanl.out ${OutRaw}/RAWINS_DOMAIN${DomId}

else
    bsplit -6000000000 rawanl.out  small.raw.
    set NUM = 1
    echo ls small.raw.* >| hold
    set test = `source hold`
    foreach split ( $test )
        mswrite -t $RetPd $split \
            ${OutRaw}/RAWINS_DOMAIN${DomId}_BSPLIT_${LETTERS[$NUM]}
        echo mswrite -t $RetPd $split \
            ${OutRaw}/RAWINS_DOMAIN${DomId}_BSPLIT_${LETTERS[$NUM]}
        @ NUM ++
    end
    rm small*
endif
```

mswrite:

This is a NCAR local command used to copy an existing UNICOS disk file to MSS.

bsplit:

This is Cray executable used to split Cray binary files to a size specified (in this example, the size is 6,000,000,000 bytes). The size is limited by how many bytes MSS allows in a file (currently the limit is 6,000,000,000 bytes).

D.6 terrain.deck

```
# QSUB -r TERRAIN          # request name
# QSUB -q reg              # job queue class
# QSUB -eo                # stdout and stderr together
# QSUB -lM 40Mw           # maximum memory
# QSUB -lT 1000           # time limit
# QSUB                   # no more qsub commands
#
ja
set echo
#
#
```

```
# *****
# ***** terrain batch C shell *****
# ***** V2 System *****
# *****
#
if ( $?ENVIRONMENT ) then
    echo "environment variable defined as $ENVIRONMENT"
else
    setenv ENVIRONMENT INTERACTIVE
    echo "environment variable defined as $ENVIRONMENT"
endif
#
if ( $ENVIRONMENT == BATCH ) then
    cd $TMPDIR
endif
#
# This should be the user's case or experiment name.
# set the TERRAIN MSS outputs pathname and the retention period
# (for example MM5V2/TEST/EXP1/...). Note that there is no / in front
# of the pathname.
#
    set ExpName = MM5V2/TEST/EXP1
    set RetPd   = 365                # Retention period in days for MSWRITES
#
# set host user and machine names to remote copy the terrain plots
# to users' local machine, where username is the users login name
# on their local machine, domain.host is the local machine's address.
#
    set Host    = username@host.domain:/usr/tmp/username
#
# set GLOBAL30S = TRUE, if you want to use global 30 sec. elevation data:
#
# set GLOBAL30S = TRUE
# set GLOBAL30S = FALSE
#
# whether to create color-filled terrain/landuse plots
#
# set FillCo = FALSE
# set FillCo = TRUE
#
# set TerPlt = FALSE to create domain maps only
# set TerPlt = TRUE to create terrain/landuse output
#
# set TerPlt = FALSE
# set TerPlt = TRUE
#
# set NewLandUse = TRUE if you want to use a better landuse dataset
# derived from 30 sec vegetation data
#
# set NewLandUse = TRUE
# set NewLandUse = FALSE
#
# if NewLandUse = TRUE, select which type of input data you would
# like to use:
# USGS = Global coverage, 24 catagories
# SiB = 0 - 90N, 60W - 180W, 16 catagories (same as used in Eta)
#
if ( $NewLandUse == TRUE ) then
    set VegType = USGS
# set VegType = SiB
endif
#
if ( $TerPlt == FALSE ) then
    set GLOBAL30S = FALSE
    set NewLandUse = FALSE
endif
#
# TERRAIN MSS output file pathname
#
    set OutTerr = $ExpName
#
# Do you want to create an additional IEEE copy of the output?
# IEEE data are used on workstations.
#
```

```

# set OutIEEE = no
# set OutIEEE = yes
#
# ----- GET TERRAIN TAR FILE -----
#
