Computing New Diagnostic Fields in MPAS-Atmosphere Simulations

Michael G. Duda NCAR/MMM

This material is based upon work supported by the NSF National Center for Atmospheric Research, a major facility sponsored by the U.S. National Science Foundation and managed by the University Corporation for Atmospheric Research. Any opinions, findings and conclusions or recommendations expressed in this material do not necessarily reflect the views of NSF.

Motivation

As the number of people using MPAS-Atmosphere increased to even a very modest number, it was recognized that we needed some structured way of introducing the computation of new diagnostics

We wanted a framework that could handle:

- Instantaneous diagnostics
- Cumulative diagnostics
- Extreme value diagnostics
- Or anything that looked like the above from a computational standpoint!

Diagnostics should be able to change in response to modifications of the streams that write them, too.

Introduction

Broadly, there are five stages in the computation of diagnostics like those types listed on the previous slide:

- 1. Setup Pre-allocate arrays that will be needed by the diagnostic during the simulation, initialize values, etc.
- 2. Update Accumulate values, update extrema, etc.
- 3. Compute Divide by the accumulation period to get mean values, compute instantaneous fields, etc.
- 4. Reset After writing the diagnostic, zero-out accumulation arrays, etc.
- 5. Cleanup Deallocate any memory that was allocated by the diagnostic

Other than Setup and Cleanup, how do these phases fit into the sequence of a model timestep?

Critically, we need some way for a diagnostic to determine whether it will be written out in a given timestep!

Along with the diagnostics framework, a utility module has been written that will tell a diagnostic:

- Whether its field will be written in a given timestep
 - Generally called from the Compute phase
- How many output streams include its field

In terms of code structure, where do we add diagnostics?

- The idea is that all diagnostics should be implemented as self-contained modules
- All diagnostics modules should reside in the same place

In terms of code structure, where do we add diagnostics?

- The idea is that all diagnostics should be implemented as self-contained modules
- All diagnostics modules should reside in the same place

```
MPAS-Model/
    src/
        core atmosphere/
           diagnostics/
                                                           These files serve
               Makefile
                                                            as the interface
               Registry diagnostics.xml
                                                          between your new
                                                          diagnostic and the
               mpas atm diagnostics manager.F
                                                            rest of MPAS
           dynamics/
            inc/
           physics/
           Registry.xml
           utils/
```

- 1. Define new namelist options and fields in a new Registry_<your_diagnostic>.xml file. Add a #include statement for this new Registry section in the Registry_diagnostics.xml file.
- 2. Create a new module for the diagnostic.
- 3. Add calls to your diagnostic's *setup*, *update*, *compute*, *reset*, and *cleanup* routines in the main diagnostic driver.
- Update the Makefile to compile your new diagnostic module.

The README file in the diagnostics/ subdirectory describes the step-by-step process to adding a new diagnostic

1. Define the maximum SWDOWN field in a new Registry_swdown.xml file

2. Include Registry_swdown.xml in Registry_diagnostics.xml

```
<!-- SW radiation diagnostics --> #include "Registry_swdown.xml"
```

3. Write the setup, update, and reset routines for the diagnostic:

```
subroutine swdown_setup(all_pools)
type (MPAS_pool_type), pointer :: all_pools
type (MPAS_pool_type), pointer :: diag_physics
call mpas_pool_get_subpool(all_pools, 'diag_physics', diag_physics)
call mpas_pool_get_array(diag_physics, 'gsw', gsw)
call mpas_pool_get_array(diag_physics, 'gsw_max', gsw_max)
```

```
gsw_max(:) = 0.0
```

end subroutine swdown_setup

Not shown in the code above is the declaration of gsw and gsw_max pointers as module variables...

3. Write the setup, update, and reset routines for the diagnostic:

```
subroutine swdown update()
```

```
gsw max(:) = max(gsw max(:), gsw(:))
```

end subroutine swdown_update

3. Write the setup, update, and reset routines for the diagnostic:

```
subroutine swdown_reset()
use mpas_atm_diagnostics_utils, only : mpas_field_will_be_written
if (mpas_field_will_be_written('gsw_max')) then
    gsw_max(:) = 0.0
end if
```

end subroutine swdown reset

After adding a couple of lines to the Makefile, we're ready to compile MPAS-Atmosphere and try out our new diagnostic

We'll test it by:

- Outputting the gsw_max field every 60 minutes
- Outputting the gsw_max field every 1440 minutes

Our test simulation will start at 2010-10-23 at 00 UTC, and we'll look at the output that we get at 2010-10-24 at 00 UTC...

Example: 60-minute output interval

Example: 1440-minute output interval

MPAS-Atmosphere provides a framework that enables many types of diagnostic fields to be implemented in a modular way

The file

MPAS-Model/src/core_atmosphere/diagnostics/README summarizes the steps to implementing a new diagnostic.
