4th IPCC Model Projections of the Palmer Drought Severity Index

MOTIVATION

- Snowpack is the most important water source in the western US
- Climate models show warm & dry conditions in the SW US. However, these models do not resolve the complex terrain and orographic effects well
- Regional climate models show inconsistent snowpack projections

Colorado's Headwaters

Continental-scale river basins whose headwaters reside in the Colorado region:

- Platte River
- Arkansas River
- Colorado River
- Rio Grande River

(courtesy Col. Div. Water Res.)

Key Questions: Will the predicted increase in snowfall due to a warmer, moister climate be enough to offset the enhanced melting and sublimation due to the warmer temperatures? Will this be sufficient to maintain river flow at current levels, or is it expected to decrease? How high resolution of the regional climate model do we need to answer these questions?

Model Domain

Full Domain

Sub-domain

Verification with SNOTEL data

Brooklyn Lake
SNOTEL station
snowgauge

- Site run on battery, recharged by solar panel on tower
- Data transferred each day using meteorological technology
- Sensors at site:
Snow pillow
Snow gauge
Snow depth (ultrasonic)

Methodology

- **Study of impact of varying model resolution**
 - Ten day model runs at 20, 10, 4, and 2, km resolution
- **High-res regional current and future WRF climate model simulations verified by SNOTEL data .**
 - Six month snowfall and snowpack simulations for an average, above average, and below average winter season.
 - Multi-year cold-season snowpack simulations in a GCM-projected warmer climate.

Computer Time Award

- 500,000 GAUs on IBM Power 575 (Bluefire) as part of the Accelerated Science Discovery competition

Ten Day WRFV3 Model Run with NARR

23 November 2002 – 4 December 2002

WRFV3 simulations at 20, 10, 4, and 2 km horizontal resolution

Average precipitation at high elevation SNOTEL sites

WRF3V vs SNOTEL : Accum. Precipitation for 23 Nov. 2002 - 4 Dec. 2002

Simulations were performed with WRFV3 using NARR model data for lateral boundary conditions. Thompson microphysics scheme was used for all the simulations.

Model data points are averages of values at four grid points nearest to the individual SNOTEL sites. There were 100 operational SNOTEL sites in the subdomain (shown right) in 2002.

Full Water Year Historical Simulations

- 6 month period from Nov. 1 – May. 1
- Four years simulated:
 - 2001/2002 (dry)
 - 2003/2004 (average)
 - 2005/2006 (average)
 - 2007/2008 (wet)
- Model setup and design
 - WRF Model (version 3)
 - A single domain: 1200x1000 km²; 2 km grid spacing; 45 levels
 - PBL scheme: MYJ
 - Noah land-surface model
 - CAM longwave & shortwave scheme
 - Thompson et al. cloud microphysics scheme
 - The 3-hourly, 32-km NARR data provide the initial and lateral boundary conditions

Future Climate Sensitivity Run

Motivation

Prohibitively expensive to run high-resolution models at the desired resolutions for decades to generate a statistically meaningful future climate (time-slice method)

Approach:

Add a climate signal to the current-day high resolution simulations. Primary impact of the climate signal is to warm and moisten the troposphere.

Signal derived from future climate model runs.

Future Climate Sensitivity Run Setup

- Climate sensitivity run performed using modified boundary conditions to the NARR analysis of a current water year following the approach by Kawase et al. 2008 and Hara et al. 2008.
 - Modified initial and boundary conditions obtained by subtracting the 10 year average monthly conditions of 10 2050s CCSM3 A1B scenario runs from the average of 10 1990s CCSM3 present climate runs averaged over the month and added to the NARR initial and boundary conditions from a current water year (temperature, relative humidity, geopotential height, and wind).
- Modified initial and boundary conditions show a 1.5 C temperature increase over Colorado, and an increase of mixing ratio on the order of 10%. RH in the simulation similar to the control.
- WRF model run using the new boundary conditions for high resolution simulations of two full water years

Summary

- Comparison of WRF high resolution simulations of annual snowfall to SNOTEL observations over the Colorado Headwaters regions show very good agreement if resolutions below 6 km are used.
 - WRF model water year accumulated snowfall at SNOTEL sites agrees are within 20% of the observations for 80% of the 112 Colorado Headwaters sites
 - Some areas of disagreement due to the WRF model creating too much snow to the lee of steep topography
 - Other disagreements under investigation
- 18 km resolution runs underestimated SNOTEL snowfall by 25-50% as a result of:
 - Terrain smoothing and associated spreading of the precipitation horizontally as a result of a broader and weaker updraft
 - Not resolving mesoscale circulation patterns such as Conditional Symmetric Instability which produce snow bands.

Colorado Headwaters Summary

- High resolution simulations (2 km horizontal) of annual snowfall suggests that current global and regional model estimates of snowfall at the ground (18 km resolution and higher) underestimate high elevation snow by 25-50%, and over estimate low elevation snow fall by a similar amount.
- A sensitivity run simulating the impact of enhanced atmospheric moisture due to global warming from an ensemble of CCSM centered on 2050 suggests that high elevation snowpack increases by ~10-25% under this scenario.
- Future simulations will focus on:
 - Verifying the hydrology of the model runs, including SWE and streamflow
 - Applying the verified high resolution model to future climate impacts using a Time Slice approach
