

An aerial photograph of a vast, rugged mountain range covered in snow. The peaks are sharp and jagged, with deep shadows in the valleys. The sky is a pale blue, and the overall scene is one of a high-altitude, cold environment.

Snow and Ice Enhancements to the RUC Land-Surface model in WRF and WRF-based Rapid Refresh

**Global Systems Division (ESRL/GSD)
Tanya Smirnova, John Brown, Stan Benjamin**

12th Annual WRF Users' Workshop, 20 June 2011

Land-Surface Models (LSM) in WRF:

sf_surface_physics (max_dom):

0 – no surface temperature prediction

1 – thermal diffusion scheme
num_soil_layers = 5

2 – unified Noah land-surface scheme
num_soil_layers = 4

3 – RUC land-surface model
num_soil_layers = 6 or 9

7 – Pleim-Xiu scheme (only ARW)
num_soil_layers = 2

RUC LSM has been implemented in operational Rapid Update Cycle (RUC) at NCEP since 1998:

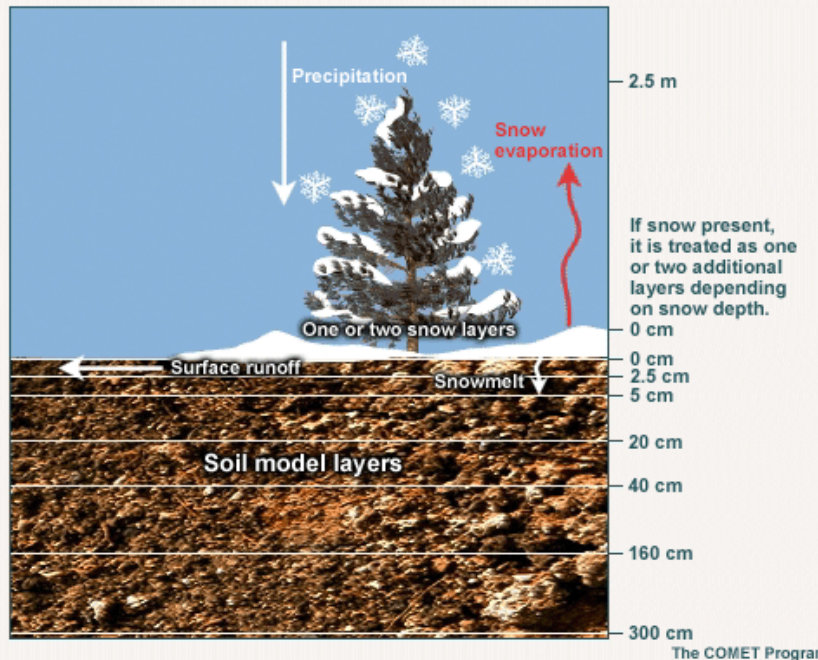

- more accurate lower boundary for weather prediction in RUC (aviation/severe weather)

- *13-year long* record of *surface grids* provided to GCIP/GAPP community for climate studies

Cycling of soil moisture, soil temperature, snow cover, depth, temperature in RUC 1h cycle since 1998

Snow model in RUC-LSM

1. One- or two-layer snow model (threshold – 3 cm of snow water equivalent)
2. Changing snow density depending on snow depth, temperature, compaction parameter
3. Two-iteration snow melting algorithm; snow can be melted from the top and bottom of snow pack
4. Prescribed amount of liquid water (13%) from melting can stay inside snow
5. Melted water infiltrates into soil and forms surface runoff

6. Mixed phase precipitation
7. Falling snow can be intercepted by the vegetation canopy until the holding capacity is exceeded

Modified 2-layer snow model –

- changed vertical structure of the snow model
- snow albedo reduction for thin snow layer – “patchy” snow

Motivation – correct excessively cold temperatures at night (with clear skies, low winds) over thin snow layer;
– improve estimation of the snow melting rate.

Aspects of RUC LSM that differ from Noah LSM:

❑ Fluxes in the surface layer

- **layer approach** to energy and moisture budget with **implicit** solution of energy and moisture budgets
- **bare soil** evaporation based on surface moisture gradient
- transpiration (simpler formulations, less sensitivity to parameters)

❑ Soil model

- **higher vertical** resolution, thinner top layers
- **prognostic soil moisture variable** ($\theta - \theta_r$)
- some differences in numerical approximations

❑ Snow model in RUC LSM versus Noah bulk snow layer

- treatment of **mixed phase** precipitation
- **two iterations in melting** algorithm, time dependent **snow/ice albedo**

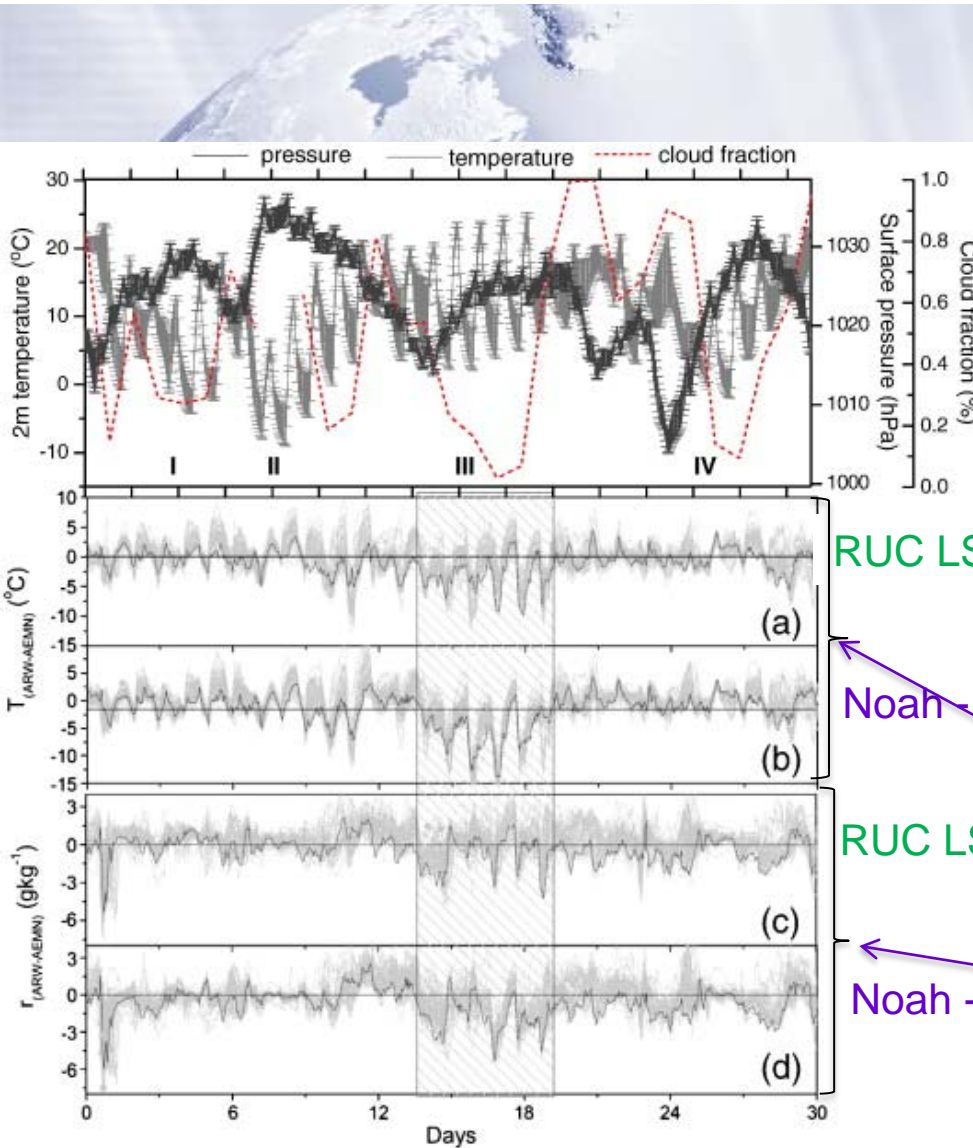

❑ Frozen soil physics algorithm and treatment for sea ice

Role of land surface parameterizations on modeling cold-pooling events and low-level jets

1. Seo B., Byon J., Choi Y. : *Sensitivity evaluation of wind fields in surface layer by PBL and LSM parameterizations using WRF over the Korean Peninsula*, American Geophysical Union, Fall Meeting 2010, abstract #A41F-0164

“LSM comparisons indicate that the RUC model performs best in predicting 10 m and 80 m wind speed. It is found that MYJ (PBL) _ RUC (LSM) simulations yielded the best results for wind field in the surface layer.”

2.

EPA “RARE” Project:

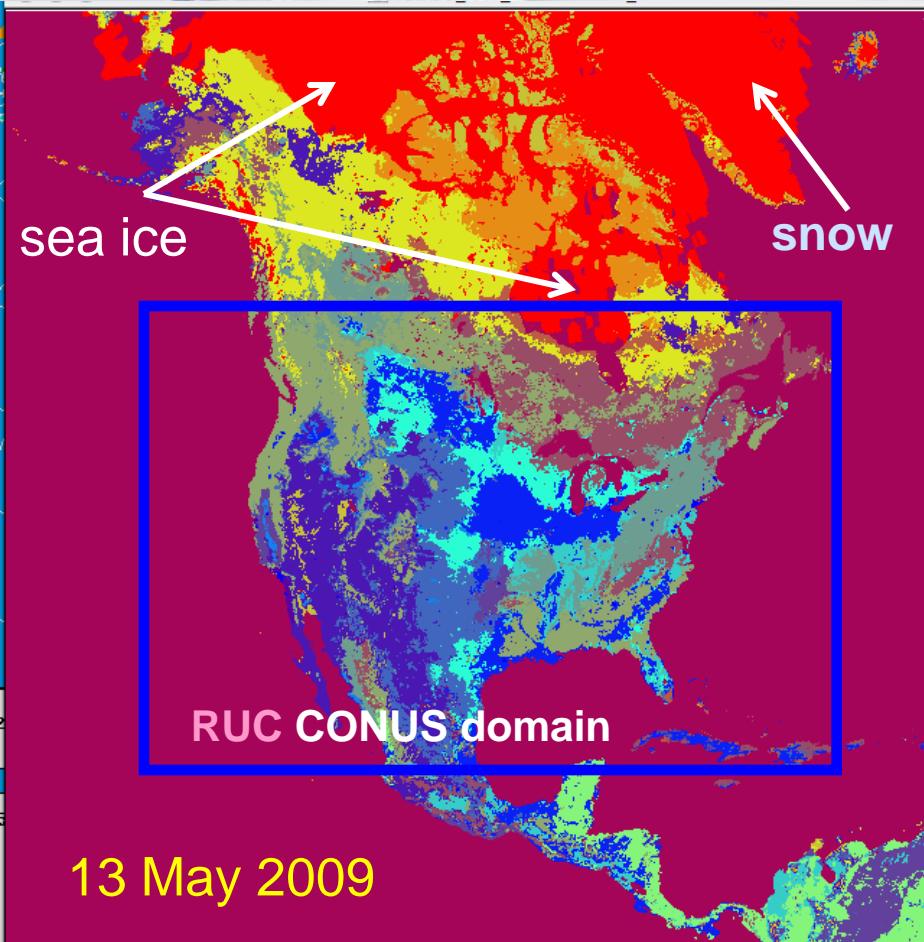

*Testing CMAQ air quality model
for wintertime Fairbanks episodes*

- **RUC LSM is better overall than Noah for the coldest periods of this case study**
 - Cold bias during period of cooling temps and light snow possibly due to microphysics
 - Strong diurnal cycle in Feb. and coldest inversions possibly a result of better resolved snow radiation flux

➤ **Based on statements in published results** performed for different applications and in different parts of the world (*Persian Gulf areas, Korea, Equatorial East Africa, Mexico, Iberian Peninsula, Italy, France, Russia, India and different regions of United States*) :

- **RUC LSM** provides better diurnal cycle, performs well for stable conditions in summer, provides good predictions of surface wind and better PBL heights, favors heavier rainfall, has better performance in deserts, provides better predictions of inversions over snow and under radiative cooling conditions
- **Noah LSM** performs better in unstable conditions, has good predictions of near-surface mixing ratio, provides better performance for higher elevations
- Sensitivity to **combination** of physics: LSM, PBL, microphysics and radiation schemes

Further RUC LSM modifications motivated by WRF-based Rapid Refresh (RR)

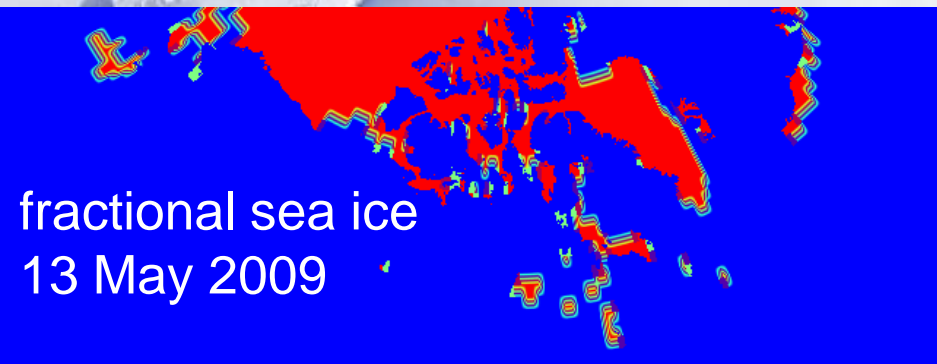

- RR polar application in Canada and Alaska including extended permafrost tundra zones and snow covered sea ice
 - new treatment for sea ice in RUC LSM
 - temperature dependence of snow and ice albedo

RR USGS land use types

Sea Ice Treatment in RUC LSM (available since WRF revision 3.2.1)

Sea Ice is initialized in WRF-based **Rapid Refresh (RR)** from **NESDIS** snow/ice data or from **GFS**

Old sea ice in RUC LSM

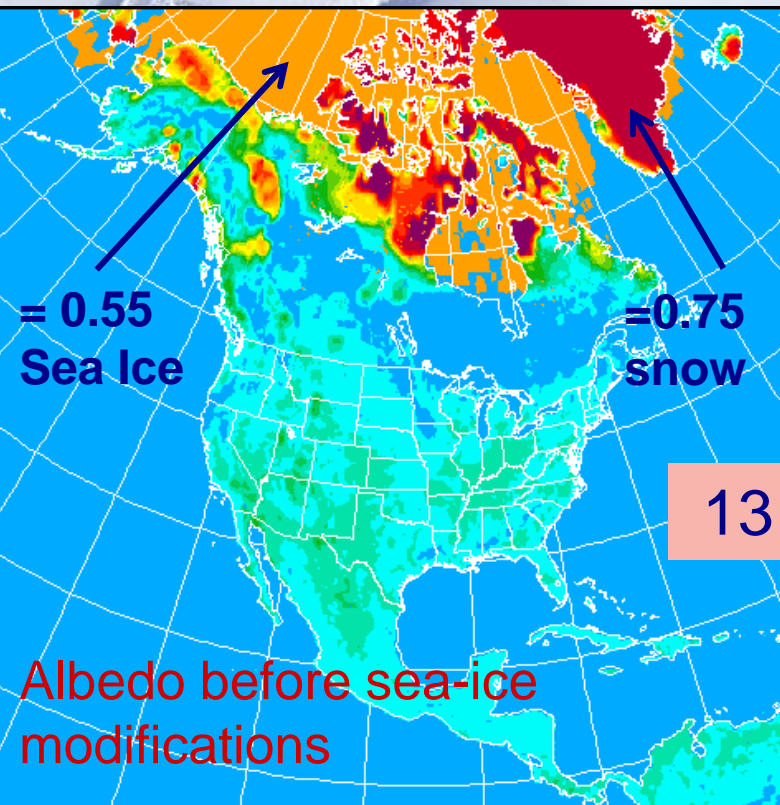

- Skin temperature is prescribed to be equal to temperature at the 1st atmospheric level
- No snow on sea ice

New sea ice treatment in RUC LSM

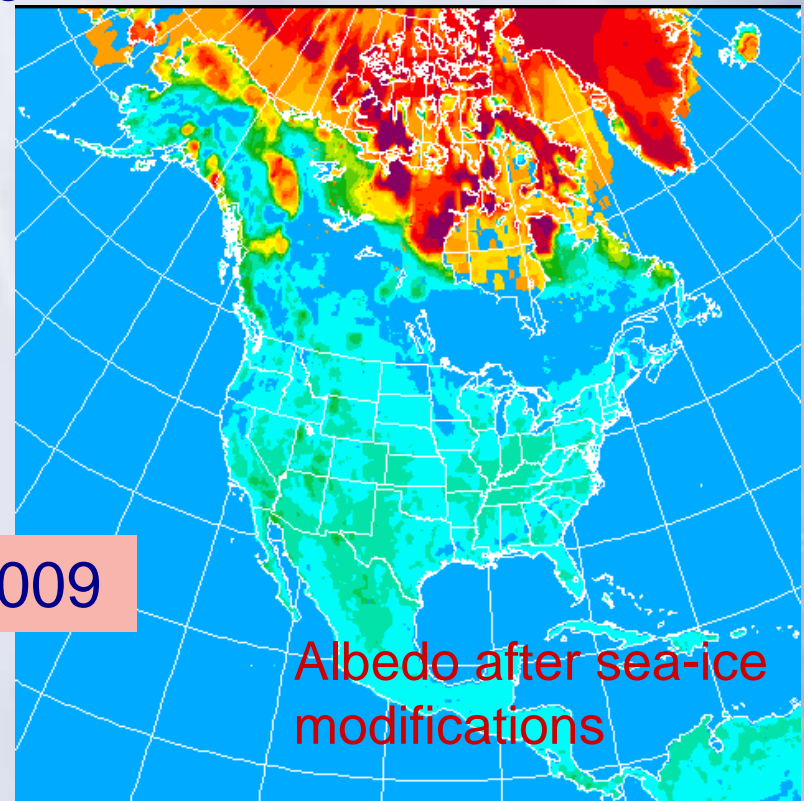

- Solution of surface energy budget and heat diffusion equation in ice
- Snow accumulation/melting on the sea ice surface
- Snow/Ice Albedo - function of snow/ice surface temperature
- Option of fractional sea ice
- No melting, drifting or building new sea ice

Snow and ice albedo in RR with use of RUC LSM

1. Albedo specified from NESDIS monthly climatological albedo interpolated to a current day
2. Albedo updated for snow and ice using static field of WRF maximum snow albedo

13 May 2009

3. "Patchy" Snow plus temperature dependence of snow/sea ice albedo when $T_{\text{snow/ice}} > -10^{\circ}\text{C}$ (min albedo when $T = 0^{\circ}\text{C}$)

3. "Patchy" Snow – albedo reduced when snow fraction < 1

Shading - vertically integrated cloud water and ice mixing ratio

Valid 18 UTC 16 June 2011

Future plans

- ❑ Continued testing and validation of **RR** and **HRRR** with the use of **MODIS** landuse categories
- ❑ Effects of mosaic approach to specification of landuse and soil parameters on surface verification at different resolutions (13km **RR** and 3-km **HRRR**)
- ❑ Consider modifications to evapotranspiration algorithm (use of LAI, transpiration function, etc)
- ❑ Committing recent **RUC LSM** modifications to the WRF Repository; follow up on WRF community LSM sensitivity studies
