

Introduction

- 37 warm season convective events from 2006-2010 were simulated using WRF3.1.1 (ARW) with 3 km grid spacing (Thompson microphysics, NAM IC/LBC) and integrated for 24h
- Simulated events were classified using 10 morphologies, and then compared to observed morphologies
- Larger scale environment documented at initiation using 20 km RUC analyses 1 hour prior to initiation
- Objective skill score based on degree of mode agreement and timing was developed and used to rate events

Modes used included 9 used by Gallus et al. (2008) plus one mixed-complex (MC) mode added.

For objective verification, normalized time scales used for both simulated and observed systems, then merged (example below).

| Mode | Time (UTC) | Length (hours) | Normalized time |               | Mode | Time (UTC) | Length (hours) | Normalized time |               |
|------|------------|----------------|-----------------|---------------|------|------------|----------------|-----------------|---------------|
| BL   | 2054       |                | 0               | Initiation    | CC   | 2000       |                | 0               | Initiation    |
| NS   | 0425       | 7.52           | 0.50            |               | NS   | 0330       | 7.5            | 0.47            |               |
| BE   | 0724       | 10.50          | 0.70            |               | NL   | 0600       | 10             | 0.63            |               |
|      | 1200       | 15.10          | 1               | End of period | TS   | 0930       | 13.5           | 0.84            |               |
|      |            |                |                 |               |      | 1200       | 16             | 1               | End of period |

Observations

WRF model

| T <sub>1</sub> | T <sub>2</sub> | ΔT   | Obs. | WRF |
|----------------|----------------|------|------|-----|
| 0              | 0.47           | 0.47 | BL   | CC  |
| 0.47           | 0.50           | 0.03 | BL   | NS  |
| 0.50           | 0.63           | 0.13 | NS   | NS  |
| 0.63           | 0.70           | 0.07 | NS   | NL  |
| 0.70           | 0.84           | 0.14 | BE   | NL  |
| 0.84           | 1              | 0.16 | BE   | TS  |

Group match – modes in same general classification (linear, cellular) but not exact =1/2 point over time interval

Detailed match – exact modes = 1 point over time interval

- Final score for example case would be  $0.5 \cdot 0.47 + 0.5 \cdot 0.16 + 0.13 = 0.45$
- Note: penalty was introduced if simulated initiation or dissipation of system was more than 3 hours different from that observed
- Average score for full sample was 0.49

20km RUC hourly analyses used to obtain initial environment conditions (1 hr prior to initiation)

- Surface-based CAPE
- Mixed-layer CAPE
- 0-3 km bulk shear
- 0-6 km bulk shear
- Potential temperature at surface
- Potential temperature at level of maximum theta-E

General Results

- WRF forecasted more cellular modes and fewer linear modes than observed

|            | IC | CC | BL | BE  | TS | NS | PS | LS | NL | MC | Total |
|------------|----|----|----|-----|----|----|----|----|----|----|-------|
| Radar      | 6  | 7  | 24 | 21  | 19 | 17 | 1  | 0  | 17 | 3  | 115   |
| Model      | 8  | 16 | 24 | 8   | 13 | 22 | 1  | 0  | 16 | 1  | 109   |
| Difference | 2  | 9  | 0  | -13 | -6 | 5  | 0  | 0  | -1 | -2 | -6    |

- WRF usually simulated a cellular mode when a cellular mode was observed

| Observed mode | Comparisons | Detailed matches | Group matches |
|---------------|-------------|------------------|---------------|
| IC            | 7           | 3 43%            | 6 86%         |
| CC            | 11          | 5 45%            | 9 82%         |
| BL            | 34          | 17 50%           | 24 71%        |
| Total         | 52          | 25 48%           | 39 75%        |

- WRF struggled more to predict linear modes

| Observed mode | Comparisons | Detailed matches | Group matches |
|---------------|-------------|------------------|---------------|
| BE            | 44          | 7 16%            | 26 59%        |
| TS            | 29          | 7 24%            | 17 59%        |
| PS            | 1           | 0 0%             | 1 100%        |
| NS            | 24          | 8 33%            | 10 42%        |
| LS            | 0           |                  |               |
| Total         | 98          | 22 22%           | 54 55%        |

- WRF struggled to predict nonlinear and the mixed-complex modes

| Observed mode | Comparisons | Detailed matches |
|---------------|-------------|------------------|
| NL            | 29          | 10 33%           |
| MC            | 6           | 1 17%            |
| Total         | 35          | 11 31%           |

- Bow Echoes and Trailing Stratiform Squall Lines were most poorly predicted, with a failure to produce stratiform rain a common problem, along with problems organizing the convective line

- WRF often showed NS as cellular and BL missed at initiation

|                                     | All cases | Cases with score > 0.5 | Cases with score < 0.5 |

Statistically significant at 90% confidence level

Skill at predicting mode seems to depend on strength of 0-6 km shear, and possibly also max theta value (CAP strength) or strength of low-level stable layer

Summary

- Model was more accurate at matching cellular modes than linear modes (especially TS, BE)
- Strong 0-6 km shear and cool potential temperatures at the level of maximum theta-E at initiation associated with better-scoring cases
- Weaker 0-6 km shear and stable conditions near the surface at initiation associated with timing issues
- Individual case studies (not shown) suggest problems in simulating near-storm shear may explain model failures at depicting mode
